

Catalog of Linkage Propositions for a System of Systems Processes GST

Dr. Len Troncale, Dept. of Biology, & Institute for Advanced Systems Studies
California State Polytechnic University
Pomona, CA, 91768
ltroncale@csupomona.edu

Assumptions and Limits on a General Theory of Systems

- Please see previous poster or reprint collection (1978 on) entitled “Intro to A System of Systems Processes (SSP)” as a general theory of systems for a more complete description of this model and approach. This poster is focused only on further elaboration and discussion of the Linkage Proposition (LP) part of that theory.
- Connectedness of entities is the fundamental assumption underlying research on systems, in particular, as well as systems-in-general.
- However, many past efforts at establishing general theories have not explicitly described the “connections” between things and rendered them discrete & workable for those new to the field.
- Further, due to the wiring of the human brain and habits of perception, humans focus mostly on rather static, physical entities and not on the more abstract and dynamic PROCESSES by which the entities act. These interactions may be very large in number which are very difficult for humans to follow at one time.
- The SSP-LP-GST is designed to overcome these obstacles.

What are Linkage Propositions?

- The main goal of the SSP is ID & documentation of the interactions between systems processes in great specificity and quantity, in much greater detail than other GST’s.
- We call these interactions “Linkage Propositions” (hereafter LP’s) because they tie together (unify, synthesize) the systems processes (linkages) & because they are not proven in the scientific sense in every system yet, so remain as only partially proven “conditionals.” They are stronger than conjectures in math because some proof exists.
- To become a candidate LP, strong evidence has to be documented for the interaction in some range of well-studied particular, real systems. But the full range of their transdisciplinarity need not yet be determined. Their specification will help doing this.

- The basic description of a unit LP is shown above as a basic dyad, a line connecting two nodes. Each node is a systems process (one of the isomorphies); each line is the mutual interaction, influence, or relation between them (one LP).
- These interactions are between minimal energy, time, space, material isomorphs, so they also are minima as shown in the cartoon at left. Given enough time, and sufficient trials, new systems not only “find” the systems processes, they also spontaneously “fall into” the LP’s.

- Each Linkage Proposition states how one systems process influences another as in “positive feedback is a partial cause of (necessary condition for) growth and development.” Or “coupled feedbacks are a partial cause of oscillations.”
- LP’s are most easily expressed in language. Our convention at present is to show each systems process as an underlined phrase connected by a standard phrase chosen from our Association Classes that describes the mutual influence.
- Sometimes the LP requires more than two systems processes working together.
- Each systems process has many influences on and is influenced by many other systems processes. This illustrates the “entitiation” concept of Gerard, one of the Founders of the ISSS. It also explains the non-linear behavior of many systems.

Some Sample Linkage Propositions

- Here are some general examples of Linkage Propositions we are studying.....
- Transitions/Phases/Modes are in part the result of Symmetry Breaks in Linkages.
- Symmetry Breaking is a partial cause of Scalar Emergence.
- Hierarchical Structure is a partial result of Scalar Emergence.
- Diffusion Limited Aggregation (DLA) is a type of Systems Flow
- Non-Equilibrium Thermodynamics is a necessary condition for DLA.
- Diffusion Limited Aggregation is a partial cause of Fractal Structure.
- Non-Equilibrium Thermodynamics is a necessary condition for Fractal Structure.
- Boundary Conditions are a partial cause of the Exclusion Principle.
- Concrescence Ratio is a partial cause of new Boundary Conditions.
- Notice that several of this small example set are interrelated and so result in paths, or cycles, or subclusters within the complex networks of 100’s of LP’s in the System of Systems Processes. For example, note the chain from symmetry breaks to emergence to phase states or from DLA to Fractals. Also note that the very existence of these specific interaction sets leads to fascinating new questions.

- When many dozens of LP’s are shown connecting systems processes, the graphic at right emerges as a “image” of the SSP.
- This diagram only shows a small sample of the LP’s acting on just four of the isomorphic systems processes.
- It shows that this GST not only describes how networks arise and are maintained, but actually is a complex network itself.
- The image at right is a generic dynamic representative of many systems; it is a “template” for systems dynamics. As a template, it can be used to represent and/or analyze many manifest, real systems.
- It can also be used to determine how real systems sometimes malfunction (see posters on Systems Pathology).

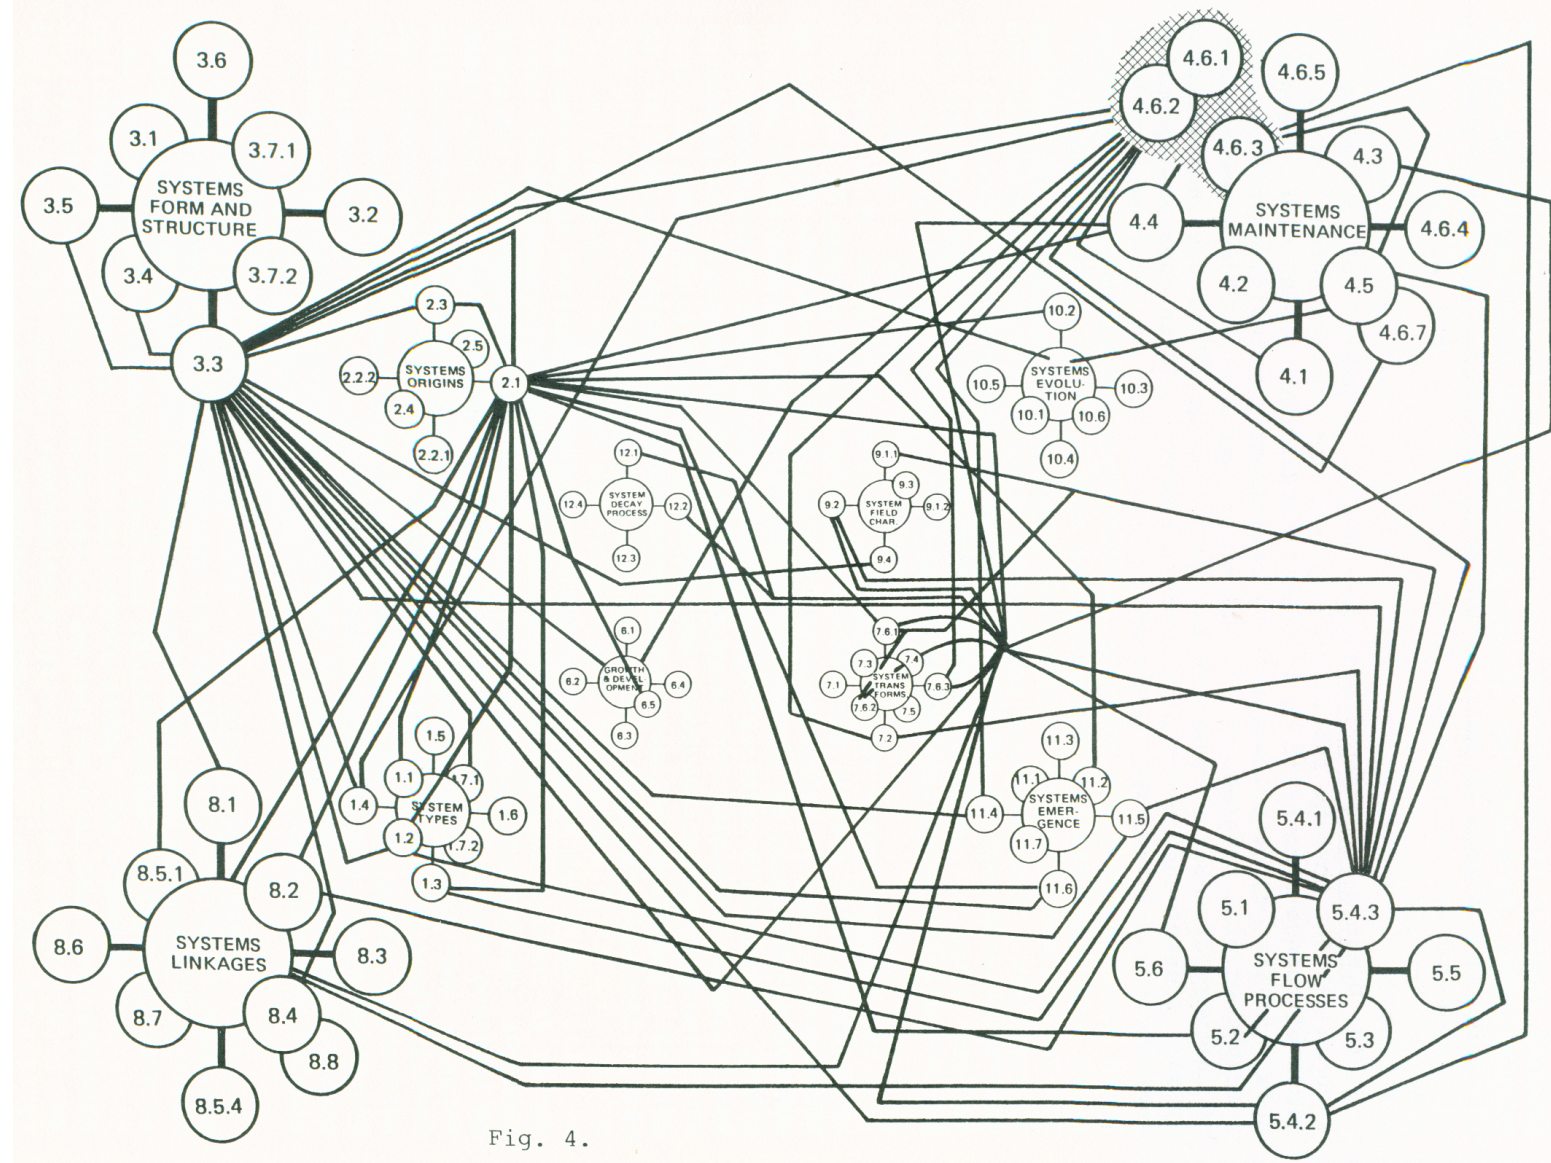

Fig. 4.

Dependency Analysis of Linkage Propositions

- Designing discrete interaction statements like the LP’s makes it possible to do a search for which of the isomorphic systems processes is most fundamental.
- We call this a “prerequisites list” or a “dependency analysis” because it describes which LP’s cannot occur without others first occurring. We still maintain that all systems processes included are axiomatic and all are needed in “mature” systems. But even within the axiomatic set there are inner dependencies. These become a new set of Linkage Propositions.
- For example, Binding Interactions require Boundary Conditions require Flows.
- For example, Oscillations require Coupled Feedbacks require the presence of Positive Feedbacks and Negative Feedbacks which require Cycling which requires Flows.
- But as an additional example, Flows requires Potential Fields.
- So from these we can suggest which systems processes are more funamental.

How Are LP’s Different from Text Descriptions?

- So how is the Linkage Proposition portion of the System of Systems Processes different from other text based discussion of how systems work, or other treatments such as mathematical expositions?
- They are much more concise than long text explanations.
- They are restricted to single directional or mutual influences so are more discrete.
- They are clearly not as concise as formal mathematics treatments, but they are understood and communicable to a wider audience.
- The statements are not necessarily less rigorous than formal equations though because they are closely tied to empirical studies of particular systems.
- They enable diversity of assembly just as discrete words do in language.

Based on Systems Integrated Science

- The pictures at right depict the scales of seven natural sciences studied in 270 case studie for the Integrated Science GE Program. The conventional science behind these are the sources for the Linkage Proposition statements. So extensive refereed literatures exist that support the interactions that are codified in the LP’s. These literatures extend from the physical sciences, thru the biological sciences, to the social and applied sciences as indicated in the accompanying student posters for selected systems processes and their Linkage Propositions.

Hierarchical Outline of Linkage Propositions

- Below we have encoded 174 sample Linkage Propositions formulated since the beginning of the SSP in 1978. These were included in the workbook accompanying the Pre-Conference Workshop on “Intro to Systems Science Praxis” at the 50th Annual ISSS Meeting.
- Because of their early coining, these are being updated to current standards & formats.

1. Boundary Conditions.		6. Evolution & Emergence or Origins	
1.1.	To be properly defined, <u>Boundary Conditions</u> must consider the full ranges of <u>Inputs/Outputs</u> acting on the bounded system.	6.1.	<u>Neutrality Quest</u> causes systems structures to form.
1.2.	Defining the <u>Boundaries</u> of a system is identical to identifying the included systems as components, entities, elements or subsystems.	6.2.	<u>Neutrality Quest</u> causes a small number of pocket of <u>Negentropy</u> to form, and drives their <u>Evolution</u> .
1.3.	<u>Boundary Conditions</u> must be known to properly define internal versus externally generated <u>Goals/Purposes</u> for the system.	6.3.	<u>Neutrality Quest</u> is caused by the fundamental <u>Dualisms</u> (counterparties) on each level of the <u>Metahierarchy</u> .
1.4.	<u>Restructuring</u> can only be defined if <u>Boundary Conditions</u> are clearly recognized.	6.4.	<u>Dichotomies</u> such as <u>Open/Closed</u> , <u>Internal/External</u> , and <u>Input/Output</u> are not <u>Counterparties</u> because though opposite, they are not necessarily always equal or acting in opposition to each other.
1.5.	<u>Boundary Conditions</u> must be known to define whether a system is open or closed.	6.5.	The ability of <u>Feedback</u> to act as a coupling between widely separated levels of the <u>Hierarchy</u> contributes to hierarchical relativity.
1.6.	<u>Intrasystem Coupling</u> contributes to the establishment of <u>Boundary Conditions</u> .	6.6.	<u>Counterparty</u> (dualism) is in part cause of the <u>Neutrality Quest</u> .
1.7.	<u>Life Cycles</u> are a type of <u>Boundary Condition</u> that specifically defines temporal <u>Boundaries</u> .	6.7.	<u>Counterparty</u> acted upon by <u>Neutrality Quest</u> can sometimes cause <u>Transgressive Equilibrium</u> , or the <u>Origin</u> of a new level of entities and a new portion of the <u>Hierarchy</u> .
1.8.	<u>Transitions/Phases/Modes</u> are transformations in the predominant types of subsystem interrelationships that in turn change some but not all of the parameters used to define the system’s <u>Boundary Conditions</u> .	6.8.	A small amount of unsatisfied <u>Counterparties</u> in a population of <u>Entities</u> with mostly satisfied <u>Counterparties</u> will result in <u>Concrescence</u> .
1.9.	Identifiable <u>Boundary Conditions</u> are in part the result of achievement of <u>Steady State</u> , whether this is achieved by static or dynamic <u>Equilibrium</u> .	6.9.	<u>Concrescence</u> leads to transtemporal <u>Stability</u> .
1.10.	<u>Boundary Conditions</u> contribute in part to the cause of the <u>Exclusion Principle</u> .	6.10.	<u>Coupled</u> positive and negative <u>Feedback</u> mechanisms are a generic example of <u>Counterparty</u> .
1.11.	<u>Hierarchical relativity</u> is in part the result of applying different <u>Boundary Condition</u> parameters and getting different <u>Bounded</u> systems.	6.11.	Hierarchical organization contributes to the mechanics of unity or wholeness.
1.12.	<u>Hierarchical relativity</u> is in part the result of applying different <u>Boundary Condition</u> parameters to a set of systems resulting further in differently <u>Coupled</u> subsystems.	6.12.	<u>Neutrality Quest</u> is the result of the universal trend toward <u>Entropy</u> death.
1.13.	Patterns in <u>Incremental Trends</u> are the partial result of comparing the magnitudes of parameters of <u>Boundary Conditions</u> (and forces acting across the <u>Boundaries</u>) across the levels of modular <u>Hierarchies</u> .	6.13.	<u>Instability</u> in the form of unsatisfied <u>Counterparty</u> leads, in part, to <u>Systemic Evolution</u> .
1.14.	<u>Temporal Boundaries</u> of a system results from selection by its environment for the most optimal <u>Cycling</u> times. This means that temporal <u>Boundaries</u> and <u>Cycling</u> time are types of externally-generated goals of a system.	7. Hierarchical (Heterarchical) Structure & Function	
1.15.	Recognition that a system has <u>Components/Entities/Elements</u> that are sometimes called subsystems is the same as recognizing the system as <u>Decomposable</u> .	7.1.	<u>Hierarchically</u> organized systems, especially of the modular type, are <u>Decomposable</u> .
1.16.	For a <u>Component/Entity/Element</u> to be properly defined it must be placed in the appropriate <u>Hierarchical</u> level.	7.2.	<u>Hierarchical</u> organization is highly <u>Negentropic</u> .
1.17.	For a <u>Component/Entity/Element</u> to be properly defined all of its <u>Linkages/Interrelationships</u> must be documented.	7.3.	Flatness in a <u>Hierarchy</u> is <u>Stable</u> in static systems, but <u>Unstable</u> in dynamic systems.
1.18.	This <u>Diversification Processes</u> are a partial cause of <u>Transgressive Equilibrium</u> . Systems organization allows a greater variety and higher level of behavior than can be achieved by any of the systems elements alone (paraphrased from Asakoff, 1971).	7.4.	Hierarchical organization increases the probability of transtemporal stability of over-larger complexes through systemic <u>Evolution</u> and thus causes higher levels of <u>Negentropy</u> .
1.19.	<u>Boundary Conditions</u> of a system are in part the result of the strength and duration of the linkages between its subsystems.	7.5.	<u>Hierarchical</u> organization contributes to systemic <u>Growth</u> and <u>Development</u> and allowable <u>complexity limits</u> .
1.20.	The participation of <u>Entities/Components/Elements</u> as subsystems in a supersystem is in part the cause of their transtemporal stability.	7.6.	The deterministic aspect of <u>hierarchical organization</u> (once probabilistically evolved) enhances the deterministic aspect of <u>Cycling</u> .
1.21.	In cases of <u>Synergy</u> , <u>Boundaries</u> are expanded from tightly drawn around the bounded entity to a much wider <u>Boundary</u> including the other participants in the <u>Synergy</u> .	7.7.	<u>Counterparty</u> and <u>Neutrality Quest</u> acting together cause <u>Transgressive Equilibrium</u> , which is synonymous with genesis of a new level of the <u>Hierarchy</u> . (Systems’ <u>Evolution</u>)
1.22.	Intra-system <u>Coupling</u> contributes to the establishment of <u>Boundary Conditions</u> .	7.8.	Gaps in <u>Hierarchical Levels</u> are the result of the appearance of new magnitudes of <u>Boundings</u> strength, distance, time, and energy, due to the appearance of new unsatisfied <u>Counterparties</u> .
1.23.	The mechanics of unity/wholeness is in part the result of <u>Boundary Conditions</u> .	7.9.	Subsystems are the same as <u>Components/Entities/Elements</u> of a system while the system so formed is a <u>Component/Only/Element</u> of the next level in the <u>Hierarchy</u> .
1.24.	<u>Boundary Conditions</u> are involved in the distinction between insulated and non-insulated linkages.	7.10.	<u>Hierarchical</u> levels determined in part by <u>Incremental</u> parameter trends are in part the cause of the <u>exclusion principle</u> .
1.25.	Temporal capture of <u>Energy Flux</u> must occur within the <u>Boundary</u> of a system.	7.11.	The transtemporal <u>Stability</u> of hierarchical organization is enhanced by cross-level <u>Feedback</u> .
1.26.	<u>Concrescence Ratio</u> can lead to the establishment of new <u>Boundary Conditions</u> by causing, in part, new levels of <u>Transgressive Equilibrium</u> .	7.12.	Each new <u>Hierarchical Level</u> achieves a new <u>Transgressive Equilibrium</u> .
1.27.	<u>Concrescence Ratio</u> can lead to the establishment of new <u>Boundary Conditions</u> as well as the associated features of <u>Transgressive Equilibrium</u> .	7.13.	Each new <u>Hierarchical</u> level is in part the result of a new <u>Counterparty</u> .
1.28.	<u>Boundary conditions</u> in part result from the establishment of a <u>Steady State</u> , whether it is the result of either static or dynamic <u>Equilibrium</u> .	7.14.	Each new <u>Hierarchical Level</u> contributes to the sudden <u>Emergence</u> of a new quality of systems over and above that of the levels below. (<u>Transgressive Equilibrium</u>)
2. Linkage and Interrelations		7.15.	<u>Transgressive Equilibrium</u> is in part the cause of levels in <u>Hierarchy</u> .
2.1.	<u>Transitions/Phases/modes</u> are in part the result of alterations in the <u>Linkages</u> among subsystems of a system.	7.16.	<u>Synergy Breaks</u> are a partial cause <u>Hierarchical Structure</u> (Clustering).
2.2.	<u>Inputs/Outputs</u> are classifications of the broader category of <u>Linkages</u> . These classifications are based on the function they perform in the self-reference space of the system.	7.17.	<u>Diffusion Limited Aggregation</u> is a partial cause of <u>Hierarchical Structure</u> .
2.3.	<u>Linkages</u> across levels in different <u>Hierarchies</u> cause three-dimensional, topological <u>Hierarchies</u> .	7.18.	<u>Recycling</u> of systems components/entities after systems <u>lifecycle</u> decay contributes to <u>Equilibrium</u> of the next higher level of <u>Hierarchy</u> .
2.4.	<u>Linkages</u> are the medium by which subsystems become systems, and systems become supersystems.	8. Fractal Structure	
2.5.	Periodic <u>Cycles</u> are the result of special types of <u>Linkages</u> , which are deterministic in the sense that the same sequence of <u>States</u> always obtains and the same specific state is always found in the specific time zone of the periodicity	8.1.	<u>Non-Equilibrium Thermodynamics</u> is a necessary condition for <u>Fractal Structure</u> .
2.6.	Temporal capture of <u>Energy Flux</u> is a function of <u>Linkages</u> which results in transtemporal stability	8.2.	<u>Diffusion Limited Aggregation</u> is a partial cause of <u>Fractal Structure</u> .
2.7.	Similar <u>Linkage</u> strengths, times, and distances (incremental parameter trends) characterize the <u>Entitiation</u> within a level of the <u>Hierarchy</u> and help to define the levels empirically and non-humanocentrically.	9. Energy Flow	
2.8.	Similar <u>Linkage</u> strengths, time, and distance determine what is inside and what is outside a system in applications of the <u>Exclusion Principle</u> .	9.1.	The systems that get the most energy and use it the most effectively are the systems that are the most likely to survive.
2.9.	<u>Linkages</u> influences what is considered inside and outside a system and so results in recognition of its <u>Boundary Conditions</u> .	9.2.	<u>Neutrality Quest</u> is a special case of <u>Energy Flows</u> and provides them with direction.
2.10.	<u>Linkages</u> must be known to define whether or not a system is open or closed.	9.3.	<u>Energy flows</u> derive from <u>counterparties</u> seeking their complement to achieve a <u>neutrality balance</u> .
2.11.	The <u>Uncertainty Principle</u> is caused by the number of <u>Linkages</u> being never entirely knowable	10. Duality	
2.12.	All <u>Linkage Propositions</u> are generic cases of real systems <u>Linkages</u> indicating how the attributes of systems are produced in nature.	10.1.	<u>Uncoupling of Dualities</u> is a partial cause of <u>Synergy Breaks</u> .
2.13.	Temporal capture of <u>Energy Flux</u> can only be found in <u>Open Systems</u> .	10.2.	Spontaneous breakage of <u>Duality-based Coupling Forces</u> results in <u>Symmetry Breaks</u> and is a partial cause of <u>Phase Transitions</u> .
2.14.	<u>Positive And Negative Feedback</u> mechanisms are often found <u>Coupled</u> together.	10.3.	<u>Symmetry Breaks</u> are a partial cause of <u>Gas Discontinuities</u> .
3. Feedback		10.4.	<u>Instability</u> and its opposite <u>Stability</u> are paired in nature as partial cause of one of the most fundamental of <u>Counterparties</u> (<u>Duality</u>).
3.1.	Goal-seeking <u>Feedback</u> is in part the cause of <u>Teleological/Purposeful</u> systems.	10.5.	A small amount of unsatisfied <u>Counterparties</u> in a population of entities with mostly satisfied <u>Counterparties</u> will result in <u>Concrescence</u> and <u>Emergence</u> of <u>Hierarchical Structures</u> .
3.2.	Goal-seeking <u>Feedback</u> is in part the cause of <u>Oscillations</u> .	10.6.	<u>Coupled Positive and Negative Feedback</u> mechanisms are a generic example in <u>Counterparty</u> .
3.3.	Goal-changing <u>Feedback</u> is a characteristic feature of <u>Evolving</u> systems of the biological/ecological type.	11. Fields	
3.4.	<u>Feedback</u> paths may be within levels of a <u>Hierarchy</u> or between levels.	11.1.	<u>Field Dynamics</u> neutralizes the consequences of <u>Complexity</u> (Computational Explosion).
3.5.	<u>Feedback</u> is one of the few types of <u>Linkages</u> that operates across widely separated levels of the <u>Hierarchy</u> .	12. Entropy	
3.6.	<u>Feedback</u> from the environment of the system is in part the cause of shifts in phases and modes.	12.1.	For certain types of <u>Open Systems</u> , the rate of <u>Entropy</u> production tends to a minimum. (From Rapoport, in Kiril, 1971)
3.7.	<u>Feedback</u> is a special type of <u>Coupling</u> between subsystems of a system.	12.2.	<u>Closed Systems</u> are characterized as proceeding irreversibly to <u>Entropy</u> and disorder
3.8.	Positive <u>Feedback</u> contributes to <u>Growth Processes</u> .	12.3.	<u>Entropy</u> is an expression of the more universal <u>Neutrality Quest</u> .
3.9.	Negative <u>Feedback</u> contributes to <u>Equilibrium</u> .	12.4.	Components avoid <u>Entropy</u> death by <u>Restructuring</u> .
3.10.	<u>Coupled Positive And Negative Feedback</u> generates the sigmoid curve characteristic of all systems <u>Growth Processes</u> and decay <u>Cycles</u> .	12.5.	If <u>Entropy</u> death results in a structure, then that structure is <u>Metastable</u> ?
3.11.	Coupled positive and negative feedback contributes to transtemporal stability.	12.6.	Types of systems such as astronomical, physical, and chemical tend toward <u>Entropy</u> .
3.12.	Coupled positive and negative <u>Feedback</u> mechanisms are in part the cause of the <u>Oscillations</u> around the ideal median typical of <u>Cycles</u> .	12.7.	As there is <u>Entropy</u> loss to all <u>Closes</u> (energy, informational, etc.) and <u>Linkages</u> , the <u>Linkages</u> that survive the longest are those that are based on <u>Transformations</u> from a <u>State</u> of great available energy to lesser. This relationship is partly the source of incremental trends across <u>Hierarchical</u> levels such as decreasing numbers and increasing size. It also explains the probabilistic nature of transtempore <u>Stability</u> .
3.13.	There is no <u>Feedback</u> in static regulation.	12.8.	<u>Open systems</u> can locally increase their order or <u>Negentropy</u> if energy is constantly supplied for throughput.
3.14.	Either positive or negative <u>Feedback</u> can be found in dynamic regulation.	12.9.	<u>Open Systems</u> can reverse the universal tendency toward <u>Entropy</u> in their local space/time continuum only if energy is constantly supplied.
3.15.	Positive and negative <u>Feedback</u> mechanisms are often found linked together as a partial cause of dynamic <u>Equilibrium</u> .	12.10.	<u>Negentropy</u> requires permeable <u>Boundary Conditions</u> .
3.16.	Positive <u>Feedback</u> is a partial cause of amplification of rates of <u>Growth Processes</u> and <u>Development Patterns</u> and <u>Lags or Phase Processes</u> .	12.11.	Systems with internally derived goals actually design <u>Negentropy</u> in the environment. Systems with externally derived goals cannot although cluster of such systems increase the probability of <u>Negentropy</u> in the local area.
4. Equilibrium		12.12.	<u>Restructuring</u> leads to <u>Negentropy</u> .
4.1.	Dynamic <u>Equilibrium</u> is the same as <u>Oscillations</u> around an ideal median of system behaviors, where the limits of behavior which the environment of this system will allow leads to a version of the limit <u>Cycle</u> for the system.	12.13.	Transtemporal <u>Stability</u> is a case of <u>Negentropy</u> .
4.2.	<u>Transgressive Equilibrium</u> is in part the cause of levels in <u>Hierarchy</u> .	12.14.	Types of systems such as biological, sociological, and man-made tend toward <u>Negentropy</u> in the short-term, but succumb to <u>Entropy</u> in the long-term.
4.3.	<u>Transgressive Equilibrium</u> is, in part, the result of the probabilistic, random nature of subsystem <u>Interactions</u> to form systems	12.15.	Temporal capture of <u>Energy Flux</u> , when coupled with <u>Restructuring</u> , increases <u>Negentropy</u> .
4.4.	Instability in the form of unsatisfied <u>Counterparty</u> leads, in part, to systemic <u>Evolution</u> .	12.16.	Coupled <u>Feedback</u> favors <u>Negentropy</u> .
4.5.	<u>Equilibrium</u> is a mechanism for achieving transtemporal stability.	12.17.	Both dynamic and <u>Transgressive Equilibrium</u> increase <u>Negentropy</u> in a system.
4.6.	Static <u>Equilibrium</u> is found in <u>Open Or Closed Systems</u> , while dynamic <u>Equilibrium</u> is found only in <u>Open Systems</u> .	12.18.	<u>Energy</u> required for maintenance is proportional to the <u>Negentropy</u> of a system. (Odum and Odum, 1976)
4.7.	<u>Restructuring</u> is a mechanism for achieving <u>Equilibrium</u> .	12.19.	As <u>Negentropy</u> increases in systems the effectiveness of these systems in utilizing energy increases as well as their ability to export a variety of energy sources.
4.8.	Temporal capture of <u>Energy Flux</u> contributes to achievement of <u>Equilibrium</u> .	12.20.	<u>Entropy Measures</u> are a <u>Pure Opposite Counterpartier</u> to complexity of a system.
4.9.	<u>Equilibrium</u> is, in part, the result of dynamic regulation.	12.21.	<u>Uncoupling of Dualities</u> is a partial cause of <u>Entropy</u> .
4.10.	<u>Metastability</u> is destructive of <u>Equilibrium</u> and transtemporal <u>Stability</u> .	12.22.	<u>Symmetry Breaks</u> are a partial cause of <u>Entropy</u> .
4.11.	<u>Recycling</u> of systems <u>Components/Entities</u> after systems <u>lifecycle</u> death contributes to <u>Equilibrium</u> of the next higher level of the <u>Hierarchy</u> .	12.23.	<u>Neutrality Quest</u> is in part the result of the universal trend toward <u>Entropy</u> death.
4.12.	<u>Instabilities</u> in small amounts built upon larger magnitudes of stability are the most conducive to systems level <u>Evolution</u> , which, in turn, yields new <u>Transgressive Equilibria</u> and transgressive attributes (new qualities).	12.24.	<u>Hierarchical</u> organization is highly <u>Negentropic</u> .
4.13.	<u>Instability</u> is the opposite of <u>Stability</u> , and their pairing in nature makes them one of the most fundamental of <u>Counterparties</u> .	13. Synergy	
4.14.	<u>Non-Equilibrium Thermodynamics</u> is a necessary condition for <u>Diffusion-Limited Aggregation</u> .	13.1.	<u>Synergy</u> is a special type of positive <u>Feedback</u> characteristic of purposive systems.
5. Cycles and Oscillations		13.2.	<u>Synergy</u> contributes to <u>Negentropy</u> .
5.1.	Consonant <u>Cycling</u> is a special case of <u>Synergy</u> .	13.3.	<u>Synergy</u> sometimes results (cooperates?) in achieving a <u>Transgressive Equilibrium</u> .
5.2.	<u>Cycling</u> reduces the <u>Energy Flow</u> necessary to maintain a <u>Negentropic</u> , deterministic succession of <u>States</u> in a system.	13.4.	<u>Synergy</u> increases the ability of the cooperating entities to achieve to achieve <u>Restructuring</u> .
5.3.	<u>Instability</u> to <u>Stability</u> back to <u>Instability</u> is a flow typical of life <u>Cycles</u> and <u>Recycling</u> of <u>Components/Entities/Elements</u> .	13.5.	<u>Synergy</u> is a special relationship of <u>Input/Output</u> processes such that the components sharing the relationship have achieved an unusual focusing of their outputs on each other as stimulatory input. (Aspects of interesting)
5.4.	Goal-seeking <u>Feedback</u> is in part the cause of <u>Oscillations</u> .	13.6.	<u>Synergy</u> is the result of an intensified set of <u>Linkages</u> between a group of entities.
5.5.	<u>Metastability</u> is a partial inhibitor of <u>Recycling</u> of <u>Components/Entities/Elements</u> .	13.7.	Does <u>Synergy</u> enhance transtemporal <u>Stability</u> ?
5.6.	As <u>Cycling</u> requires continuous <u>Energy Input</u> for its maintenance, it is found most often in <u>Open Systems</u> and is <u>Negentropic</u> in nature.	13.8.	<u>Synergy</u> is a type of <u>Coupling</u> .
5.7.	<u>Cycling</u> (of the life <u>Cycle</u> variety) is the same as the temporal <u>Boundaries</u> of the system in question.	13.9.	<u>Synergy</u> maximizes <u>temporal captures of energy flux</u> .
5.7.1.	Life <u>Cycles</u> are a type of <u>Boundary Condition</u> , specifically defining temporal <u>Boundaries</u> .	13.10.	<u>Synergy</u> in <u>Purposive</u> systems disfavors both <u>Instability</u> and <u>Metastability</u> ?
5.8.	<u>Recycling</u> of components of a system is a special type of <u>Linkage</u> between the system and other systems in its environment.	13.11.	<u>Synergy</u> may result from consonance in <u>Cycles</u> .
5.9.	<u>Cyclic</u> behavior is planned <u>Instability</u> .	13.12.	<u>Synergy</u> contributes to <u>Transitions/Phase Shifts/Accelerated</u> modes.
5.10.	<u>Synergy</u> between systems which are a large number of levels distant from each other in the natural <u>Hierarchy</u> provide for greater <u>Stability</u> on the lower levels. For example, animal life <u>Cycles</u> in alignment with the geological/seasonal <u>Cycles</u> .	13.13.	<u>Synergy</u> may act within or between levels of the natural <u>Metahierarchy</u> .
5.11.	Deterministic sequences of subsystem <u>Transformations</u> lead to periodic <u>Cycling</u> .	13.14.	<u>Synergy</u> implies directionality of systems <u>Energy Flows</u> when in purposive systems, and also in non-purposive?
5.12.	Reductions in required <u>Energy Flow</u> for <u>Cycling</u> are partially dependent on contributions of <u>Recycling</u> of components to <u>Autopoiesis</u> of systems in succeeding <u>Hierarchical</u> levels.	13.15.	<u>Synergy</u> is favored by <u>Neutrality Quest</u> selection of some ranges of <u>Concrescence Ratio</u> over others.
Non-Equilibrium Thermodynamics is a necessary condition for Diffusion Limited Aggregation		13.16.	<u>Synergy</u> intensifies purposiveness of teleological systems while having no such effect on non-teleological systems.
Symmetry Breaks are a partial cause of Entropy		Unassigned:	
As Cycling requires continuous Energy Input for its maintenance, it is found most often in Open Systems and is Negentropic in nature		Non-Equilibrium Thermodynamics is a necessary condition for Diffusion Limited Aggregation	
Symmetry Breaks are a partial cause of Entropy			

- The SSP & its LP’s would have multiple other uses. It could be used....
- As a comprehensive knowledge base for more detailed and improved systems education programs.
- As a source of novel information & insight for rapidly expanding, well-funded new specialties such as Systems Biology & Earth Systems Sciences.
- To provide a detailed basis for a unified Sciences of Complexity, and for new fields like Systems Allometry & Systems Pathology.
- To provide practical design alternatives for a wide range of Systems Design Applications of all types.
- To improve systems models and systems simulations of real and artificial systems.
- To improve communications among the wide range of systems workers from many different disciplines by providing standards and translations among the different systems studied.
- To enrich the meaning & understanding of each isomorphic systems mechanism or process.
- To assess the rigor and completeness of alternative general theories of systems & the completeness & rigor of alternative real systems models and simulations.
- To improve our understanding of the sources of complex behavior in complex systems.

Some Uses & Applications of LP’s
